CSEIT

# Steady state analysis of M/M/1 Queue with Two-Phase, Server Time-Out and Breakdowns 

V. N. Rama Devi<br>Department of Humanities and Basic Sciences, GRIET, India

#### Abstract

This paper analyzes $\mathrm{M} / \mathrm{M} / 1$ vacation two-phase queueing model with server Start-up, Time-out and Breakdowns. Customers arrivals are assumed as Poisson process and be given batch mode in the first phase followed by individual models second phase. Arrivals during batch service are allowed to enter the batch without Gating. After providing the second phase of service to all customers individually, server returns to first phase to serve the existing customers followed by individual service. If no one presents, then server waits for a fixed time ' C ' is called server Time-out. If units arrived during this fixed time, then the server starts the cycle again by providing them batch service followed by individual service, otherwise after expiration of fixed time he takes a vacation. The server comes back from vacation, after N -customers are accumulated. The server passes a random period as pre-service procedure after coming back from vacation. During individual service the server is susceptible to random failures. Various performance measures are evaluated in steady state. Cost function is established to define the threshold and sensitivity analysis is also presented through numerical examples.

Keywords: Vacation, Two-phase, Pre-service, Time-Out and Server Breakdown.

## I. INTRODUCTION

We deal with the optimal analysis of $\mathrm{M} / \mathrm{M} / 1$ two-phase vacation queueing system with server startup, timeout and breakdowns. The two-phase M/M/1 queueing model was first presented by Krishna and Lee(1990).Doshi (1990) studied the two-phase M/G/1 queueing system. Vacation queueing models by using the probability generating function technique was first introduced by Levy and Yechiali. Kim and Chae (1998) analyzed the two-phase queueing system with N -policy. Oliver C.Ibeet.al studied $\mathrm{M} / \mathrm{M} / 1$ multiple vacation queueing system with differentiated vacation. Olive C.Ibe introduced the timeout concept and he derived mean waiting time of the vacation queue with timeout.

There are many papers in Two-Phase; this paper is an extension to improve server's utility with the concept of Timeout.

## II.THE SYSTEM AND ASSUMPTIONS

Arrivals are assumed to follow Poisson process with mean arrival rate $\lambda$ and join the first phase of batch service. The server delivers service to all the customers with mean service rate $1 / \beta$. On completion of batch service, everyone of this batch receive individual service with mean rate of $1 / \mu$. In the individual service phase, the server may fail with a failure rate $\alpha$. It can be instantly repaired with a repair rate $\beta$, and resumes service immediately. After this server returns to first phase to serve all the customers if any and provide
second phase then. If no one is waiting in batch queue then the server waits for a fixed time ' $C$ ' is called sever Timeout. If units arrived during this fixed time he does the service to that unit as batch service followed by individual service. If no units arrived during this fixed time, then it takes a vacation and after N customers accumulates in the batch queue and start pre-service work with mean $1 / \theta$. Once the period of startup is ended, the server starts service cycle. This cycle is shown as follows:

## III. ANALYSIS OF THE MODEL

Various steady state probabilities of the system are shown below:
$\mathrm{p}_{0, i, 0}(\mathrm{i}=0,1,2,3, \ldots)$ the server is on vacation.
$p_{1, i, 0}(i=N, N+1, N+2, \ldots)$ the server is on Start-up.
$\mathrm{p}_{2, \mathrm{i}, 0}(\mathrm{i}=0,1,2,3, \ldots)$ the server is on Time-out.
$\mathrm{p}_{3, \mathrm{i}, 0}(\mathrm{i}=1,2,3, \ldots)$ the server is in Batch service.
$p_{4, i, j}(i=0,1,2,3, \ldots$ and $j=1,2,3 \ldots)$ the server is in individual service.
$p_{5, i, j}(i=0,1,2,3, \ldots$ and $j=1,2,3, \ldots)$ the server breakdown.
The following are the satisfied system size steady state equations:
$\lambda p_{0,0,0}=C p_{2,0,0}$
$(\lambda+C) p_{2,0,0}=\mu p_{4,0,1}$
$(\lambda+\beta) p_{3,1,0}=\lambda p_{2,0,0}+\mu p_{4,1,1}$
$(\lambda+\beta) p_{3, i, 0}=\lambda p_{3, i-1,0}+\mu p_{4, i, 1} ; \quad 2 \leq i \leq N-1$
$(\lambda+\beta) p_{3, i, 0}=\lambda p_{3, i-1,0}+\mu p_{4, i, 1}+\theta p_{1, i, 0} ; \quad i \geq N$
$(\lambda+\alpha+\mu) p_{4,0, j}=\mu p_{4,0, j+1}+\beta p_{3, j, 0}++\gamma p_{5,0, j} ; j \geq 1$
$(\lambda+\alpha+\mu) p_{4, \mathrm{i}, \mathrm{j}}=\mu \mathrm{p}_{4, \mathrm{i}, \mathrm{j}+1}+\lambda \mathrm{p}_{4, \mathrm{i}-1, \mathrm{j}}++\gamma \mathrm{p}_{5, \mathrm{i}, \mathrm{j}} ; \quad \mathrm{i}, \mathrm{j} \geq 1$
$(\lambda+\gamma) \mathrm{p}_{5,0 \mathrm{j}}=\alpha \mathrm{p}_{4,0 \mathrm{j},}, \quad j \geq 1$
$(\lambda+\gamma) p_{5, \mathrm{i}, \mathrm{j}}=\alpha \mathrm{p}_{4, \mathrm{i}, \mathrm{j}}+\lambda \mathrm{p}_{5, \mathrm{i}-1, \mathrm{j}} ; \quad \mathrm{i}, \mathrm{j} \geq 1$
These equations can be solved with the following PGFs:
$G_{0}(z)=\sum_{i=0}^{N-1} p_{0, i, 0} z^{i}, G_{1}(z)=\sum_{i=N}^{\infty} p_{1, i, 0} z^{i}, G_{2}(z)=p_{2,0,0}, G_{3}(z)=\sum_{i=1}^{\infty} p_{3, i, 0} z^{i}$,
$\mathrm{G}_{4}(\mathrm{z}, \mathrm{y})=\sum_{\mathrm{i}=0}^{\infty} \sum_{\mathrm{j}=1}^{\infty} \mathrm{p}_{4, \mathrm{i}, \mathrm{j}} \mathrm{z}^{\mathrm{i}} \mathrm{y}^{\mathrm{j}}$,

$$
\mathrm{G}_{5}(\mathrm{z}, \mathrm{y})=\sum_{\mathrm{i}=0}^{\infty} \sum_{\mathrm{j}=1}^{\infty} \mathrm{p}_{5, \mathrm{i}, \mathrm{j}} \mathrm{z}^{\mathrm{i}} \mathrm{y}^{\mathrm{j}}
$$

$\mathrm{R}_{\mathrm{i}}(\mathrm{z})=\sum_{\mathrm{i}=0}^{\infty} \mathrm{p}_{4, \mathrm{i}, \mathrm{j}} \mathrm{z}^{\mathrm{i}}$ and $\mathrm{S}_{\mathrm{j}}(\mathrm{z})=\sum_{\mathrm{i}=0}^{\infty} \mathrm{p}_{5, \mathrm{i}, \mathrm{j}} \mathrm{z}^{\mathrm{i}}, \quad|\mathrm{z}|,|\mathrm{y}| \leq 1$
From using equations (1) to (12)
$\mathrm{G}_{2}(\mathrm{Z})=\frac{\lambda}{\mathrm{C}} \mathrm{p}_{0,0,0}$
$\mathrm{G}_{0}(\mathrm{Z})=\frac{\left(1-\mathrm{z}^{\mathrm{N}}\right)}{(1-\mathrm{z})} \mathrm{p}_{0,0,0}$
$G_{1}(Z)=\frac{\lambda z^{N} p_{0,0,0}}{[\lambda(1-z)+\theta]}$
$\mathrm{p}_{4,0,1}=\frac{\lambda(\lambda+\mathrm{C}) \mathrm{p}_{0,0,0}}{\mu \mathrm{C}}$
$[\lambda(1-z)+\beta] G_{3}(z)=\mu R_{1}(z)+\theta G_{1}(z)+\frac{\lambda}{C}[\lambda(z-1)-C] p_{0,0,0}$
$[\lambda(1-z)+\mu+\alpha] \mathrm{R}_{\mathrm{j}}(\mathrm{z})=\mu \mathrm{R}_{\mathrm{j}+1}(\mathrm{z})+\gamma \mathrm{S}_{\mathrm{j}}(\mathrm{z})+\beta \mathrm{p}_{3, \mathrm{j}, 0}$
$[\lambda y(1-z)+\mu(y-1)+\alpha y] G_{4}(z, y)=\gamma y G_{5}(z, y)+\beta y G_{3}(y)-\mu y R_{1}(z)$
$(\lambda+\gamma) S_{j}(z)=\alpha \mathrm{R}_{\mathrm{j}}(\mathrm{z})+\lambda z \mathrm{~S}_{\mathrm{j}}(\mathrm{z})$
$[\lambda(1-z)+\gamma] G_{5}(z, y)=\alpha G_{4}(z, y)$
The $G(z, y)$ is total p.g.f and given by
$\mathrm{G}(\mathrm{z}, \mathrm{y})=\mathrm{G}_{0}(\mathrm{z})+\mathrm{G}_{1}(\mathrm{z})+\mathrm{G}_{2}(\mathrm{z})+\mathrm{G}_{3}(\mathrm{z})+\mathrm{G}_{4}(\mathrm{z}, \mathrm{y})+\mathrm{G}_{5}(\mathrm{z}, \mathrm{y})$
The normalizing condition is

$$
\begin{equation*}
\mathrm{G}(1,1)=\mathrm{G}_{0}(1)+\mathrm{G}_{1}(1)+\mathrm{G}_{2}(1)+\mathrm{G}_{3}(1)+\mathrm{G}_{4}(1,1)+\mathrm{G}_{5}(1,1)=1 \tag{20}
\end{equation*}
$$

On solving 13-19 expressions
$\mathrm{G}_{0}(1)=\mathrm{Np}_{0,0,0}$
$\mathrm{G}_{1}(1)=\frac{\lambda}{\theta} \mathrm{p}_{0,0,0}$
$\mathrm{G}_{2}(1)=\frac{\lambda}{\mathrm{C}} \mathrm{p}_{0,0,0}$
$G_{3}(1)=\frac{\mu}{\beta} R_{1}(1)$
$\mathrm{G}_{4}(1,1)=\frac{\lambda \mu \gamma \mathrm{R}_{1}(1)+\beta \theta \gamma \mathrm{G}_{1}^{1}(1)}{\beta[\mu \gamma-\lambda(\alpha+\gamma)]}+\frac{\gamma \lambda^{2}}{\mathrm{C}[\mu \gamma-\lambda(\alpha+\gamma)]} \mathrm{p}_{0,0,0}$
$\mathrm{G}_{5}(1,1)=\frac{\alpha}{\gamma} \mathrm{G}_{4}(1,1)$
Where
$\mathrm{p}_{0,0,0}=\frac{1-\left[\frac{\lambda}{\mu}\left(1+\frac{\alpha}{\gamma}\right)+\frac{\lambda}{\beta}\right]}{\left[\mathrm{N}+\frac{\lambda}{\theta}+\frac{\lambda}{\mathrm{c}}\right]}$
Normalizing condition (20) leads to
$\mathrm{R}_{1}(1)=\frac{\lambda}{\mu}$

And is substituting in equations (24),(25) and (26) leads to
$G_{3}(1)=\frac{\lambda}{\beta}$
$\mathrm{G}_{4}(1,1)=\frac{\lambda}{\mu}$
And
$\mathrm{G}_{5}(1,1)=\frac{\lambda \alpha}{\mu \gamma}$
The steady state probabilities that the server is in different modes are
$P_{o}, P_{1}, P_{2}, P_{3}, P_{4}$ and $P_{5}$ are equals to equations (21), (22), (23), (24), (25) and (26) respectively.

## IV.EXPECTED SYSTEM LENGTH

When the server is in different modes the mean number of customers in the system are assumed $\mathrm{L}_{0}, \mathrm{~L}_{1}, \mathrm{~L}_{2}, \mathrm{~L}_{3}$, $\mathrm{L}_{4}$ and $\mathrm{L}_{5}$ are given as
$\mathrm{L}_{0}=\mathrm{G}_{0}^{\prime}(1)=\frac{\mathrm{N}(\mathrm{N}-1)}{2} \mathrm{p}_{0,0,0}$
$\mathrm{L}_{1}=\mathrm{G}_{1}^{\prime}(1)=\frac{\lambda[\lambda+\mathrm{N} \theta]}{\theta^{2}} \mathrm{p}_{0,0,0}$
$\mathrm{L}_{2}=\mathrm{G}_{2}^{\prime}(1)=0$
$R_{1}^{\prime}(1)=\frac{\lambda^{2}(\alpha+\gamma)}{\mu^{2} \gamma}$
$\mathrm{L}_{3}=\mathrm{G}_{3}^{\prime}(1)=\frac{\lambda}{\beta}$
$\mathrm{L}_{4}=\mathrm{G}_{4}^{\prime}(1,1)=\frac{\lambda\left[\lambda^{2} \beta \alpha+\mu \gamma^{2}(\lambda+\beta)\right]}{\gamma \mu \beta[\mu \gamma-\lambda(\alpha+\gamma)]}+\frac{\lambda \gamma\left[2 \lambda(\lambda+\mathrm{N} \theta)+\theta^{2} \mathrm{~N}(\mathrm{~N}-1)\right]}{2 \theta^{2}[\mu \gamma-\lambda(\alpha+\gamma)]} \mathrm{p}_{0,0,0}$
$\mathrm{L}_{5}=\mathrm{G}_{5}^{\prime}(1,1)=\frac{\lambda \alpha}{\gamma^{2}} \mathrm{G}_{4}(1,1)+\frac{\alpha}{\gamma} \mathrm{G}_{4}^{\prime}(1,1)$
The expected system length is
$\mathrm{L}(\mathrm{N})=\mathrm{L}_{0}+\mathrm{L}_{1}+\mathrm{L}_{2}+\mathrm{L}_{3}+\mathrm{L}_{4}+\mathrm{L}_{5}$

## V. SOME OTHER SYSTEM PERFORMANCE MEASURES

Let $E_{0}$ (idle), $\mathrm{E}_{1}$ (startup), $\mathrm{E}_{2}$ (timeout), $\mathrm{E}_{3}$ (batch service), $\mathrm{E}_{4}$ (individual service) and $\mathrm{E}_{5}$ (breakdown) denotes the expected length of periods of different states and long run fractions are given bellow. Also the cycle expected length is given by

$$
\begin{equation*}
\mathrm{E}_{\mathrm{c}}=\mathrm{E}_{0}+\mathrm{E}_{1}+\mathrm{E}_{2}+\mathrm{E}_{3}+\mathrm{E}_{4}+\mathrm{E}_{5} \tag{35}
\end{equation*}
$$

The fractions of time that the server in these different modes is obtained as follows:
$\frac{\mathrm{E}_{0}}{\mathrm{E}_{\mathrm{C}}}=\mathrm{P}_{0}=\mathrm{G}_{0}(1)=\mathrm{Np}_{0,0,0}$
$\frac{E_{1}}{E_{C}}=P_{1}=G_{1}(1)=\frac{\lambda}{\theta} p_{0,0,0}$
$\frac{\mathrm{E}_{2}}{\mathrm{E}_{\mathrm{C}}}=\mathrm{P}_{2}=\mathrm{G}_{2}(1)=\frac{\lambda}{\mathrm{C}} \mathrm{p}_{0,0,0}$
$\frac{E_{3}}{E_{C}}=P_{3}=G_{3}(1)=\frac{\lambda}{\beta}$
$\frac{\mathrm{E}_{4}}{\mathrm{E}_{\mathrm{C}}}=\mathrm{P}_{4}=\mathrm{G}_{4}(1)=\frac{\lambda}{\mu}$

And
$\frac{E_{5}}{E_{C}}=P_{5}=G_{5}(1)=\frac{\lambda \alpha}{\mu \gamma}$

Idle period expected length is
$E_{0}=\frac{N}{\lambda}$
Using it in (36)
$\frac{1}{\mathrm{E}_{\mathrm{C}}}=\frac{\lambda\left[1-\frac{\lambda}{\mu}\left(1+\frac{\alpha}{\bar{\gamma}}\right)-\frac{\lambda}{\bar{\beta}}\right]}{\left[\mathrm{N}+\frac{\lambda}{\hat{\theta}}+\frac{\lambda}{c}\right]}$

## VI. EVALUATION OF OPTIMAL N-POLICY ( $\mathbf{N}^{*}$ )

We construct a cost function for the present queueing model with the objective to find N that can minimize this function.

For this, we define various costs that incur per unit of time as shown below:
$\mathrm{C}_{\mathrm{h}}=$ holding cost for each customer
$\mathrm{C}_{0}=$ operational cost of server
$\mathrm{C}_{\mathrm{m}}=$ pre service cost per cycle
$\mathrm{C}_{\mathrm{t}}=$ timeout cost per cycle
$\mathrm{C}_{\mathrm{s}}=$ setup cost per cycle
$\mathrm{C}_{\mathrm{b}}=$ breakdown cost
$\mathrm{C}_{\mathrm{r}}=$ reward for the server being on vacation
The function of total expected cost per unit time is given by
$T(N)=c_{h} L(N)+c_{o}\left[\frac{E_{3}+E_{4}}{E_{c}}\right]+c_{m}\left[\frac{E_{1}}{E_{c}}\right]+c_{t}\left[\frac{E_{2}}{E_{c}}\right]+c_{b}\left[\frac{E_{5}}{E_{c}}\right]+c_{s}\left[\frac{1}{E_{c}}\right]-c_{r}\left[\frac{E_{0}}{E_{c}}\right]$

After simplification, this function attains minima where
$N^{*}=\frac{-b+\sqrt{b^{2}-4 a c}}{2 a}$
Where $a=\frac{C_{h} \mu \gamma \theta C}{2[\mu \gamma-\lambda(\alpha+\gamma)]}, \quad b=\frac{C_{h} \mu \gamma \lambda(C+\theta)}{[\mu \gamma-\lambda(\alpha+\gamma)]}$ and
$c=\frac{C_{h} \lambda[2 \lambda-\mu \gamma]}{2[\mu \gamma-\lambda(\alpha+\gamma)]}-\lambda\left[\mathrm{C}\left(\mathrm{C}_{\mathrm{m}}+\mathrm{C}_{\mathrm{r}}\right)+\theta\left(\mathrm{C}_{\mathrm{t}}+\mathrm{C}_{\mathrm{r}}\right)+\mathrm{C}_{\mathrm{s}} \theta \mathrm{C}\right]$

## VII. SENSITIVITY ANALYSIS

We perform numerical experiments to evaluate the impact of various parameters (both non-monetary and monetary) on system performance measures as well as threshold $\mathrm{N}^{*}$ as follows:

The sensitivity analysis is carried over by fixing
Non-monetary parameters as $\lambda=0.5, \mu=2.5, \beta=2, \Theta=2, \vartheta=2, \alpha=0.1, C=1$
and monetary parameters as $\mathrm{C}_{\mathrm{h}}=5, \mathrm{C}_{\mathrm{o}}=100, \mathrm{C}_{\mathrm{b}}=100, \mathrm{C}_{\mathrm{m}}=100, \mathrm{C}_{\mathrm{r}}=40, \mathrm{C}_{\mathrm{s}}=500, \mathrm{C}_{\mathrm{t}}=30$.

## Case I: Non-monetary parameters effect

* Table 1 and Figure 1 show that by increasing the value of $\lambda, N^{*}$ and $T\left(N^{*}\right)$ are increases, where as $L\left(N^{*}\right)$ is a convex function of $\lambda$.
* Table 2 and Figure 2 show that by increasing the value of $\mu, N^{*}$ and $T\left(N^{*}\right)$ are increases and $L\left(N^{*}\right)$ is decrease.
* Table 3 and Figure 3 show that by increasing the value of $\beta, N^{*}$ is constant, $T\left(N^{*}\right)$ is increase and $L\left(N^{*}\right)$ is decrease.
* Table 4 and Figure 4 show that by increasing the value of $\Theta, N^{*}, T\left(N^{*}\right)$ and $L\left(N^{*}\right)$ are decreases.
* Table 5 and Figure 5 show that by increasing the value of $\vartheta, N^{*}$ and $T\left(N^{*}\right)$ are increases, and $L\left(N^{*}\right)$ is decrease.
* Table 6 and Figure 6 show that by increasing the value of $\alpha, N^{*}$ and $T\left(N^{*}\right)$ are decreases, and $L\left(N^{*}\right)$ is increase.
* Table 7 and Figure 7 show that by increasing the value of $C, N^{*}$ and $T\left(N^{*}\right)$ are decreases and $L\left(\mathrm{~N}^{*}\right)$ is increase.
$>$ The following tables: $1,2,3,4,5,6$ and 7 shows the effect of $\lambda, \mu, \beta, \Theta, \vartheta, \alpha$ and $C$ on $N^{*}, L\left(N^{*}\right)$ and $\mathrm{T}\left(\mathrm{N}^{*}\right)$ respectively.
$>$ The following figures: $1,2,3,4,5,6$ and 7 shows the effect of $\lambda, \mu, \beta, \Theta, \vartheta, \alpha$ and $C$ on $N^{*}, L\left(N^{*}\right)$ and $\mathrm{T}\left(\mathrm{N}^{*}\right)$ respectively.

## Figure14:

## VII. CONCLUSIONS

In this model we have obtained explicit expressions for the system length of a queuing model in different modes. Sensitivity analysis made for and numerical values are presented for the different values of monetary and non-monetary parameters to illustrate the validity of the proposed model.
